CUSUM Active-Manager Monitor

Statistical Process Control for Portfolio Manager Oversight

Report generated: 09 May 2026

What is CUSUM?

CUSUM (Cumulative Sum) is a sequential change-point detection method from statistical process control, adapted for investment management by Philips, Yashchin & Stein (2003). It answers one critical question:

Has a fund manager lost their investment skill — and if so, exactly when?

The Case for CUSUM — Why CIOs Should Care

Cost of Inaction:

Retaining an underperforming manager for 3 extra years on a 500M mandate at IR=-0.3, TE=6% costs ~9M in excess losses. Early, systematic detection pays.

Faster than Rolling IR:

A trailing 3-year IR review needs 10+ years of data to distinguish skill from luck at 95% confidence. CUSUM detects persistent CHANGES in IR within 2-3 years.

Rigorous False-Alarm Control:

Threshold h is calibrated from the paper's ARL table: h=19.81 gives ~1 false alarm per 60 months (5 years) when the true IR=+0.5. Fewer spurious terminations.

Two-Sided Monitoring:

Detects skill LOSS (lower CUSUM) and unexpected skill GAIN (upper CUSUM), enabling both firing decisions and early-stage manager promotions.

Rolling Restart:

After each alarm L resets to zero — monitoring never stops. Multiple alarms build a richer signal; post-alarm returns can be tracked to validate each flag.

Industry Precedent:

SPC methods are standard in manufacturing, clinical trials, and nuclear operations. Mercer and WTW publish SPC-adjacent monitoring frameworks for manager oversight.

Actionable, Not Automatic:

An alarm triggers a structured review — not automatic termination. It forces the investment committee to ask: Is the alpha source still intact?

Reference: Philips, T., Yashchin, E. & Stein, D. (2003). "Using Statistical Process Control to Monitor Active Managers." Journal of Portfolio Management, 30(1), 86-94.

How CUSUM Works

Step-by-step mechanics of the Philips-Yashchin-Stein procedure

1

Step 1 — Log Excess Return

```
Each month:   et = ln[(1 + r_fund) / (1 + r_benchmark)]
```

Log returns are additive and symmetric — they handle compounding correctly.

2

Step 2 — EWMA Tracking-Error Estimate

```
sigma^2_t = gamma * sigma^2_{t-1} + (1-gamma) * 0.5*(et - e_{t-1})^2   [gamma=0.90]
```

Von Neumann adjacent-difference estimator: robust to drift in the mean, adapts as the manager's risk budget changes.

3

Step 3 — Monthly Information Ratio Estimate

```
IR_hat_t = (et * sqrt(12)) / sigma_{t-1}
```

Annualised IR using lagged sigma to keep the estimator approximately unbiased.

4

Step 4 — Lindley Recursion (Page's CUSUM)

```
L_t = max(0, L_{t-1} + drift)    drift = 0.5*(IR_good + IR_bad) - IR_hat_t
```

Default: IR_good=0.5, IR_bad=0.0 -> drift = 0.25 - IR_hat. L grows when manager underperforms, resets to 0 when they outperform. Upper CUSUM L_up uses drift_up = IR_hat - 0.5*(IR_exceptional + IR_good).

5

Step 5 — Rolling Alarm Rule

```
ALARM if L_t >= h   [default h = 19.81]   then reset L_t = 0 and continue
```

After each alarm L resets to zero — monitoring never stops. All alarm times are recorded; post-alarm returns validate each signal.

Alarm Threshold Reference Table (Table 2, Philips et al. 2003)

Threshold (h)	ARL — Good (IR=0.5)	ARL — Flat (IR=0)	ARL — Bad (IR=-0.5)
11.81	24.00	16.00	11.00
15.00	36.00	22.00	15.00
17.60	48.00	27.00	18.00
19.81	**60.00**	**32.00**	**21.00** *<- default*
21.79	72.00	37.00	23.00
23.59	84.00	41.00	25.00
